She was recognized for her contributions in the field of Earth system dynamics. Trumbore, who is also a director of the <u>Max Planck Institute</u> for Biogeochemistry in Jena, Germany, is a pioneer in the use of radiocarbon measurements in environmental research, particularly in how carbon flows from the atmosphere through plants and soils. She's also a leader in the application of accelerator mass spectrometry techniques to better understand the carbon cycle and climate change. "It's important to combine observations with quantitative models to develop a fundamental understanding of how organisms and ecosystems function," Trumbore said. "Through our work, we have been able to demonstrate that current global models overestimate the rate that carbon can be stored in soils, which should inform policies about how much CO2 can be safely emitted into the atmosphere by humans." The Balzan Prize includes an award of \$830,000, half of which should be dedicated to further research projects involving young scientists.
